

Digital Signal Intelligence (DSI)

A New Information Substrate for Insurance

THE CORE THESIS

An organisation’s digital footprint — how it maintains its infrastructure, who it is connected to, what it publishes, and how it behaves online — is one of the most reliable indicators of operational maturity, governance quality, and risk management capability. By systematically analysing and scoring these “digital signals”, underwriting can be automated at scale while simultaneously improving risk selection, triage, and profitability.

HOW IT WORKS

DSI replaces traditional underwriting inputs — forms, submissions, questionnaires, and documents — with externally observable, machine-readable signals that describe how an organisation behaves. Signals, including asset telemetry, public records, citations and corporate behaviour, are collected automatically, scored algorithmically, and combined into a single composite risk score that drives pricing, tiering, and automated decisioning.

Furthermore, because every signal is independently verifiable, externally observable, and machine-readable DSI enables high performance zero-touch portfolios with a low processing cost per quote and in-sequence governance and compliance checks. These factors position DSI as the first underwriting methodology designed for an agentic AI future, where autonomous systems require structured, deterministic inputs rather than subjective human judgment.

WHY WE NEED DSI

Despite decades of process innovation fuelled by billions of investment across the traditional model overall profitability has not structurally improved. This fact is proven by both the US P&C market and the Lloyd’s market, where the long-run combined ratio remains anchored around ~100%.

The reason is simple: traditional underwriting inputs are flawed. Self-reported information is inherently unstructured, variable, unsuitable for automation or AI assisted decision making, and open to mis-interpretation.

THE IMPACT

Digital-native industries routinely operate at 8–12% expense ratios. Insurance is the outlier. DSI is targeting an overall 22% decrease against the traditional model in the following areas:

Metric	Current State	DSI Target
Staff costs	12%	4%
by zero-touch underwriting and lean operations with reduced touch-points and human oversight.		
Office and Infrastructure	8%	2%
by cloud-first infrastructure and a reduced physical footprint.		
Administration	4%	1%
by embedding governance and compliance in workflows.		
Brokerage and Commissions	11%	6%
by shifting to direct placements and algorithmic triage.		

THE BOTTOM LINE

DSI changes the information substrate of insurance, rendering the root issue with the traditional model obsolete. This alternative methodology, already used by almost every industry other than insurance, unlocks zero-touch underwriting as a viable objective.
